Design Recovery
& Rebuild With
X-Analysis

Authors: Richard Downey and Stuart Milligan
Databorough Limited
May 2009
Preface

Developing tools and services for analyzing and reengineering applications for more than twenty years, has given Databorough a unique perspective on the large and complex world of legacy applications running on System i, iSeries and AS/400.

In 2005, IBM and Databorough published an IBM Redbook “Modernizing and Improving the Maintainability of RPG Applications Using X-Analysis Version 5.6”. This concepts guide you are reading now expands on the white paper ‘Modernizing RPG/COBOL/2E System i applications using X-Analysis 8’, incorporating new concepts and methods for design recovery and rebuilding of monolithic RPG/COBOL/2E applications into modern application architectures. Contact info@databorough.com for a copy of the white paper, the Redbook and trial software.

We will show in this paper how automated component generation from recovered designs can dramatically reduce the costs and risks of an application rewrite and without inheriting the legacy code’s redundancy and complexity.

Executive Summary

The knowledge and information contained in an organization’s business software is vitally important and extremely valuable but often this information covering the operation, metrics, and design of the software is tantalizingly out of reach. Without this knowledge, maintenance and changes to the system are not as efficient or effective as they could be, and the risk of failure or problems increases exponentially the larger the enhancement required. This could lead to a paralysis where changes can’t be made due to a lack of confidence in the outcome.

As many of the systems and software we are discussing here have had a long life and been marketed under various names it is worth making two orientation points:
For consistency throughout this document we will refer to System i as meaning the family of computers that grew out of IBM’s System/38 over the last twenty one years namely the AS/400, iSeries and latterly the System i and IBM i on Power.
Similarly when we refer to the RPG language we will generally mean COBOL, RPG and 2E (When we refer to 2E we mean the CA product and the various incarnations of the Synon software that preceded it).

Accurate and current information about an entire system can greatly improve the productivity of your IT staff, and reduce maintenance costs by eliminating the need to research, catalog and assemble the information manually for each service request, or modernization project.

Existing System i applications whether they are COBOL, RPG or 2E have some fairly consistent and distinct characteristics that mark them out as costly and potentially high-risk:

1. Applications tend to be large and complex
2. Little or no documentation
3. Original Designers and Developers are no longer available
4. They have been developed over many years
5. Monolithic Programming Model
6. Written in obsolete languages

Points 1 through 3 can largely be managed more effectively by investing in a product like X-Analysis to both recover the design of the application, and provide highly productive analysis tooling to compensate for the complexity of the application and the absence of the original development team.
Inconsistent programming standards and designs, significant amounts of redundant and duplicated code, and an increasingly costly demand for globally diminishing legacy development skills, are the results of points 4, 5 and 6.

This concepts guide will illustrate how X-Analysis carries out the Design Recovery process and how it can be used to build re-engineered applications from that Recovered Design.

To fully understand and appreciate the problem domain just think for a minute of two approaches to the above problems namely screen-scraping and code conversion.

Simply screen scraping the user interface with a GUI or web emulation product does not improve the situation, the application may appear slightly more ‘modern’ but the cosmetic changes still leave it with all the same maintenance and enhancement issues and it may be not much easier to use for new users.

The other common approach is code conversion i.e. line by line, syntax conversion of a legacy application, this will typically just transfer the same problems from one environment/language to another. Indeed, it will often produce source code that is less maintainable, effectively canceling out the benefit of using modern technologies and architectures in the first place. Syntax conversions are still being done by some companies and are often promoted by vendors of proprietary development tools for obvious reasons. This approach has never to our knowledge produced an optimum long-term result, despite many attempts over the last two decades.

Removing problems 4 through 6 and thus achieving sustainable and effective application modernization can only really be achieved with an application rewrite or rebuild – which is well recognized of course but usually rejected as not feasible on cost and risk grounds.

We will show in this paper how Design Recovery and automated component generation can dramatically reduce the costs and risks of an application rewrite and without inheriting the legacy code’s redundancy and complexity.

Whatever the approach to modernization, design recovery is the first step. With this understanding, developers can quickly identify the business rules and reusable designs, embedded in core business processes and restructure code, remove dead code, and create reusable components that can be enabled as services within a service-oriented architecture (SOA), or any modern application architecture. This is true, even for companies adopting code generators technologies, as their development environment.

The objective, therefore is a true modernization exercise to extract the essence or design of the legacy application and reuse these designs as appropriate in rebuilding the application, using modern languages, development tools, and techniques, tapping into more widely available skills and resources.

X-Analysis provides analysts, developers, architects and operations teams with detailed analysis and interactive diagrammatic constructs that enable rich understanding of existing applications, whether they were developed yesterday, or 30 years ago. Some companies may have a desire to keep a significant amount of design logic from the existing application design and move that to the modernized version of the application. For those situations, X-Analysis provides design extraction functionality, for automatically creating JEE* & RPG industry standard modern components and constructs as exports from the recovered designs themselves. A legacy application component can be rewritten using a combination of the JSF, EGL, Facelets, and persistence frameworks such as
Design recovery & Rebuild With X-Analysis

Hibernate, all generated by top-down automation from the recovered X-Analysis model. Because each customer situation is potentially different, the X-Analysis suite is available in different editions that suit the appropriate development stage or budget constraints of each company.

From even the most poorly structured application, the X-Analysis can recover the design logic. Whereas, for more structured applications (e.g. Synon generated applications), X-Analysis can directly extract the details of the existing model, providing an excellent base for efficient and effective design recovery and reengineering to JEE.

* Jargon Explained:

JEE – Java Extended Edition previously known as J2EE

JSF- JavaServer Faces a web application framework which uses a component-based approach to simplify development of user interfaces for JEE applications.

EGL – Enterprise Generation Language a new high level platform independent language from IBM which produces code which can be compiled into Java or COBOL.
Introduction

As we have seen gathering knowledge about System i applications is not a straightforward task for today’s generation of business analysts and developers. To illustrate that point and to fully understand the problem domain we will look at Why Design Recovery is difficult by working through the problems that X-Analysis solves in building its repository of design recovery information.

In situations where developers are not familiar with a system or its documentation is inadequate, the system’s source code becomes the only reliable source of information. Unfortunately, source code has much more detail than is needed just to understand the system, also it disperses or obscures high-level constructs that would ease the system’s understanding. X-Analysis aids system understanding by identifying recurring program features, classifying the system modules based on their purpose and usage patterns, and analyzing dependencies across the modules. This analysis provides detailed design information about the entire system, accessible to non RPG/COBOL/2E experts, and be easily updated to incorporate ongoing changes in the base system.

Whatever the business needs driving companies to modernize their applications, most want to ensure that the business logic and functional design which are core assets to the company, are preserved to varying degrees.

Design Recovery of an application can be broken down into a few logical steps or stages that represent a generic adaptable approach to any application modernization project:

Analysis, Documentation, Application Subdivision – This type of analysis represents the most common use of the X-Analysis tool across the world. On top of very powerful cross-referencing functionality, graphical, narratives or a combination of both, are used to abstract and describe the system in a simple and intuitive way, even for non-RPG/COBOL/2E experts. The legacy application can be completely documented using modern diagramming standards such as UML, Entity Relationship Diagrams, System Flow Diagrams, and Structure Charts etc. Furthermore, the legacy system can be automatically subdivided into application areas so that effective system overview & interface diagrams can be generated. The complete application documentation can then be output to a variety of third party design tools such as Rational, MS Visio, MS Word, etc. – indeed any tool capable of importing XML or DDL is supported.

Recovering an Application design – This advanced level of analysis extracts model information from the existing application. X-Analysis uses its own analysis repository, plus pattern searching algorithms, to derive relational data models, extract business rules, build UML Activity/Use/Case Diagrams, and logical screen flows. Only relevant designs need be used as a base specification for new developers to rewrite the application. The structured, repository-based format of these extracted designs, make it possible, to programmatically reuse them for rebuilding the core of a new application. This can be done with purpose-built tools, with X-Modernize or a combination of both.

Redeveloping Using a Recovered Application Design – This starts with database modernization using the recovered data model. The designs for the view, controller, and business rule logic are also extracted and reused in modern frameworks such as Hibernate, and with new JSF/Facelets and Java bean components. This option makes it possible to programmatically re-factor the existing application into modern, consumable assets and artifacts for developers to use for a
Design recovery & Rebuild With X-Analysis

system rebuild. The objective is to produce clean, well structured, industry standard code rather than messy syntax conversions with unmaintainable code.

Why Design Recovery is difficult

From the point of view of the user of X-Analysis this process of building the cross-reference repository and deriving the models happens automagically! i.e. Its just there and happens typically as part of the installation process - though it can be triggered again later on if required. However it is worth taking some time to understand this process and to see what happens, how the model is constructed and the relationships inferred.

If you think of a typical System i application it is likely to consist of a mix of RPG programs, DDS files and members for display files, database files and logical views, newer systems may have these interspersed with SQL scripts but the sum of knowledge in that system, how it works and interacts amongst its various elements is contained within those source files and compiled objects - the issue is retrieving that knowledge efficiently.

To understand and fully appreciate the problems X-Analysis solves just consider the process you would have to undertake yourself if you wanted to discover how a system operates or make changes to it. As a simple example for part of your application you have a customer details screen with no dedicated place for an email address and mobile phone numbers, the system has adapted itself to the internet age as many System i apps have done by making use of ‘extra’ and ‘notes’ ad-hoc fields. The system has coped but it has been time consuming to retrieve these details when required for marketing purposes. But there is now a budget to correct this and start to look at modernising the application and making the functionality available to more areas of the business.

You would probably first start by looking at the program and display files that handle the display and maintenance of the customer information, from that you would discover the database tables/files involved.

At this point from a simplistic point of view you have the necessary information to make the changes and they are probably not that difficult - add new fields for email and mobile phone to the database tables or rename the existing ones then modify the program and display files accordingly… but you’re probably thinking what about the rest of the system? What else uses that table? Is the display file used anywhere else? So the change has more aspects than would first appear these are just a few of the questions we have to answer:

- Scope and impact of the change - how many programs and tables are effected?
- Database changes - do we add new fields or just rename the fields and preserve the status quo? Do we know those fields were only used for email and mobile phone data?
- Database integrity - Fields destined for ad-hoc data like ‘extra information’ and ‘notes’ are unlikely to have any validation or to be even required so if migrating the existing values to new fields we can’t simply copy it over some cleansing will be required.
The process of gaining the knowledge to answer these questions may not be all that straightforward, particularly if the systems are complex or the people trying to answer them are new to the application, system or platform.

To assess the scope and impact of the change you need to find out which programs use the files/tables affected, this can be very laborious:

- Go through all source files in PDM,
- option 25 to search
- then F13 to repeat
- press enter
- type in your search term
- review results …

… and that’s just the first enquiry! Depending on the complexity and history of your systems you may have doubts that you were looking at all of the source or the latest version.

Looking into Database integrity may well throw up items like this screen shot. Where we have a number of different formats of email address and some extraneous text, similarly on the phone number list there is text and a variety of layouts. Finally we have the inevitable result of using ad-hoc fields with no validation or on screen guidance - transposed data mobile in email and vice versa.

Hopefully this section raised awareness of the problems around changing and modernizing System i applications, the issues with finding out the necessary information and how seemingly straightforward issues can be time consuming and problematic. X-Analysis is designed and optimized to make the design recovery process as straightforward as possible as the rest of this concepts guide will illustrate.

**Analysis, Documentation, & Application Subdivision**

X-Analysis builds a very detailed repository over an entire application. The repository maintains all information about application objects, their relationships and all necessary information to obtain detailed information from each object across the entire system. 20 years of ongoing development, over thousands of AS/400/iSeries/System-i applications written in all variants of RPGII/400/IV, COBOL, 2E and CL, has produced an unmatched capability to extract everything about an application from object right down to individual variables.

The repository is built automatically using a single command, and initially collects all object related information, but then parses every source member in the specified system and every source line mapping the contextual information of each variable in the system. A certain amount of

</tbody>
</table>
logical abstraction processing then takes place while building the repository to account for some of the idiosyncrasies typical in an RPG application. This includes constructs such as variable program calls, file overrides, prefixing and renaming in RPG. The repository thus represents a map of how the entire application functions right down to individual variables.

Understanding Design & Function More Easily

For efficient familiarization of an application’s structure and general function, an abstraction above the source code combined with object-to-object relational information is required. A few simple but rich types of color-coded, graphical diagrams can reveal the data flow and architecture of individual objects or parts of an entire system. This is combined with automatically derived descriptions in the form of Pseudo narratives either in the diagrams or while browsing source code. The drill-down, go-anywhere-from-anywhere, interactive nature of these interfaces in the X-Analysis client provides a unique approach to information assimilation, allowing an analyst to gather information at high level or very detailed in an efficient and intuitive manner. The application abstraction is raised one level above implementation. This instantly removes complexity caused by the idiosyncrasies of different language versions and coding practices, typical in large legacy applications developed over many years.

Here is a brief description of some of these diagrammatic constructs and views:

Structure Chart Diagram - A Structure Chart Diagram (SCD) Display gives a graphic representation of how the control passes from one program to another program within the application. This follows the call structure down the complete stack. The diagram also reveals data input objects and also automatically derives a summarized description of each of the object in the diagram. Color-coding also reveals important functional aspects such as updates, prints, and displays, which help the user to zone in on commonly, sought after details.

Data Flow Diagram - A Data Flow Diagram (DFD) is a graphical representation of a program/object where used, showing the files and programs accessed by the subject object. It is also color-coded and shows both flow of data at a high object level, and contextual information about the specific variables/parameters passed between objects.
**Design Recovery & Rebuild X-Analysis**

Figure 2 - Data Flow Diagram for a Program

Program Structure Chart - A Program Structure Chart graphically displays the sequence of calls in the program. The call could be to execute a Subroutine / Program / Module / Service Program. For details, refer to X-Analysis User Manual.

Figure 3 - Program Structure Chart for a Program

Overview Structure Chart - The Overview Structure Chart gives a snapshot of an application. It displays all the entry points to the application, and then the structure chart for each of these entry points.

Figure 4 - Overview Structure Chart for complete application

© Databorough Limited 2009
Area Flow Diagram - The Area Flow Diagram is a very useful interactive diagram that shows the linkages between files and programs within an application area, by clicking on a program we can see the files and programs it references, if we click on a file we see the programs that use it. The screen shot below shows the programs that use the Purchases file, the programs and files are colour coded to show whether they are Input/Output/Update or called or calling program.
In this example we’ve clicked on a program and can see the files it uses as Input and also the program that calls it.

RPG as Pseudo Code- With a single click, RPG can be viewed as a form of structured English or Pseudo code. Mnemonics’ are substituted with file/field/variable texts and constants or literals.

Figure 5 - RPG to Pseudo Code with a Single Click
2E as Pseudo Code - 2E action diagrams can also be displayed as pseudo-code. The information returned contains both the 2E variable names and contexts alongside the RPG/COBOL mnemonic:

```plaintext
001.00 // Calculate fat calories
002.00 DTL.Fat Calories(WFRR) = DTL.Weight(WFRR) / 0.1.Total.Weight(WFRR) * (0.1.Meals Calories(WFRL))
003.00
004.00 // Calculate 1/2 calories
005.00 DTL.Meals Calories(WFRL) = 0.5.Meals Calories(WFRL) / 2
006.00
007.00 // Calculate total calories
008.00 DTL.Meals Calories(WFRL) = DTL.Meals Calories(WFRL) + DTL.Meals Calories(WFRL)
009.00
010.00 // Send information message - 'Warnings Over 50% Fat'
011.00 MSG(USAGE1642) +INFO
012.00 END
```

**Producing Static Documentation Automatically**

Interactive analysis via a graphical client is generally the most intuitive manner in which to analyze a system, but there is often a requirement for various types of static information in the form of structured documentation. Examples of this are project documentation, auditing information, testing instructions, and customer support documentation (such as with ISV supplied business software). X-Analysis produces a number of these outputs including:

Data Flow Chart in MS Visio - Any interactive diagram produced by X-Analysis 8 in the client, can be automatically exported to MS Visio. In addition to this, an RPG/COBOL program or 2E action diagram can be produced as a data flow chart interactively while browsing the source from within X-Analysis. If the RPG program is in Pseudo Code mode, the Data Flow Chart will use the narratives from the Pseudo code. This enables non-system i technologists and analysts to assimilate information at a detailed level of the application without any dependency on RPG, COBOL or 2E experts.

Lists and Results sets – Any source, object, or impact-analysis result list can be directly exported to formatted MS Excel or Word from the client.

MS Word Project Documentation Wizard – With the use of a simple wizard, documents that might take weeks to produce manually, allow the user to select any of the graphical diagrams, lists, flowcharts, annotation and business rules summaries generated interactively by the client interface, can be collated into a single document with contents and index. This can be done for a
single object, an application area (explained in the next section), a list of objects, or an entire system. Any of these documents can then be edited and distributed as required.

**Dividing Systems into Application Areas**

Entire legacy applications are often too large to effectively comprehend or effect wholesale change. For this reason it is often necessary or helpful to sub-divide a system into application areas. The reasons and specifications for these may change with time too. X-Analysis provides facilities for subdividing an application area into groups of objects that meet user defined selection criteria. These criteria might be based on function or even generic name. X-Analysis then uses the sophisticated cross-reference information and Data Model relationships to include, automatically all related elements such as programs, displays, or files in the application area.

Application areas filters can then be used through the X-Analysis Solution Sets to view, document or reengineer as opposed to individual objects.

The Application Area diagram in X-Analysis is interactive and by clicking on different parts of your system you can see the relationships between either all parts or just the area you’ve clicked on and the areas it relates to

**Recovering an Application Design**
The concept of reusing existing code or logic is not a new one. The challenge has always been to identify, isolate, and reuse only those designs that are relevant in the new context in which they are desirable. The sheer volume of code, its complexity, and the general lack of resources to understand legacy languages, specifically RPG, represents a tragic potential waste of valuable business assets. In many cases, these expensive and well-established legacy designs have little chance of even having their relevance assessed, let alone being reused. The Design Recovery Solution Set of X-Analysis addresses this problem more directly, by isolating, indexing, and documenting those design elements that could be relevant in a modern version of the application being assessed.

Modern applications are implemented with distributed architecture. A popular standard used for this architecture is MVC or Model-View Controller. Figure 8 below shows a typical legacy and MVC architecture side by side. MVC allows for independent implementation and development of each layer, and facilitates OO techniques and code reusability rarely used in legacy applications. All these characteristics of a modern application radically improve the maintainability and agile nature. Legacy applications do have these same elements, but they tend to be embedded in and mixed up in large monolithic programs, with vast amounts of redundancy and duplication throughout. Implementing an RPG application using MVC requires that the business logic be separate from the user interface and controller logic. This can be implemented using 5250 and pure RPG (see box right), but its more likely and common implementation is using a web interface for the view, with the controller logic written in a modern language that supports web interfaces such as Java, EGL or C#. The optimum modernization result is to reduce dependency on legacy languages as much as is possible, if not altogether. To achieve this recovered design assets are reused as input to redevelop the appropriate layer.

Historically some sites have built or modified their systems to separate the presentation layer from the business logic often called n-tier or 3 tier applications these systems worked but delivered very little ‘bang for the buck’ as most of the improvements were hidden.

Recovering the Data Model

The relational model of an enterprise application is an extremely powerful piece of information and potentially valuable asset to the organization. Unlike 2E systems for almost all RPG or COBOL applications running on System i, there is no explicit data model or schema defined. By the term model, we are referring to the foreign key or relational model, not just the physical model of the database. The relational model or architecture of the database can be reused in a number of scenarios including:

- Understanding application architecture
- Data quality analysis – referential integrity testing
- Automated test data extraction, scrambling and aging
- Building BI applications or Data warehouses

X-Analysis has the unique capability of automatically deriving the explicit system data model from a legacy RPG, COBOL or 2E application. Let us have a look at this and the model reuse capability in a bit more detail.

Deriving the Legacy Data Model – X-Analysis accomplishes this by analyzing the data structures of the physical and logical files, but it then programmatically traces these through all programs that use them to verify the existence of any cross-file relationships or foreign keys. These derived relationships can also be verified by the product by performing an integrity check on the actual data. This ensures that the data of the dependent file makes a reference, to data records from the owning file. In this way, the automated reverse engineering can fully extract the data model from even the most complex legacy system.

Test Data for Modernization & Maintenance Projects – Creating and managing test data can be a labor-intensive and costly task. As a result of this, many companies resort to creating copies of entire production systems. This approach in itself can produce its own set of problems, such as excessive storage demands, longer test cycles, and often a lack of current data for testing. The relational data model is used to extract automatically, records related to those specifically selected for testing. In this way smaller, accurate test subsets can be extracted quickly and respectively, with additional functionality for scrambling sensitive production data and aging the dates in the database forwards or backwards after testing.

Recovering the User Interface

The screens of a legacy application are a classic example where the design is useful in a modernization context, and the code is not. All modern IDE’s provide powerful UI development tools. Modern UI standards and preferences for style and technology also vary from project to project. The sheer number of screens in a legacy application presents a logistical problem in recreating them manually, even with the cleverest developers and best tooling. X-Analysis lets you see what the legacy screen looked like without having to run the application which is a great time saver for people who haven’t been involved with the original application:
Screen designs of legacy applications are not just about look and feel, there are attributes, and logic embedded which from a design point of view is relevant, no matter what technology being used to implement them. These are:

- **Formats/Layouts** – Some screens may benefit from amalgamation or redesign, but table edits, and non-transaction type screens will largely remain the same, if not identical in layout.

- **Actions** – whether from sub-file options, command keys, or default enter actions, these often represent an important part of the usefulness of an application design. The mechanisms used to offer or invokes these calls may change, but where they go logically and what parameters they pass will largely remain consistent.

- **Fields/Files/Attributes** – What fields are on what screens, and where the data comes from is a requirement in any system development. Attributes of a field can also help determine what type of controls might be used in a modern UI. For example, a Boolean type might be implemented with a check box, a date with a date prompt. Again, these are simple enough to edit in modern IDE’s, but the volume associated with any large legacy application modernization can make this work prohibitive.

- **Data Model Mapping** – Validations and prompting mechanisms that ensure referential integrity in legacy applications can also be vital to extract. This is both to implement referential integrity and to provide design information for building modern prompt or selection controls such as drop downs or lists.

Naturally, it will be desirable to redesign some UI’s completely. For those programs and screens where this is not the case, the design, and mapping information can be used directly in the new version of the application, even though the UI code has been discarded.

X-Analysis extracts User Interface design information as described above and stores it as metadata in the X-Analysis repository. This is used as reference documentation for rebuilding UI’s manually, or for programmatically regenerating new View and Controller artifacts in the chosen new technology. X-Analysis currently generates a JSF/Facelets UI version as described in the section Rebuilding the View section below. The design meta-data can also naturally be used to generate new interfaces using any technology such as EGL, Ajax, RCP, C#, VB or even RPG.
Recovering Business Rule Logic

Once the system UI, data access & data model has been recovered & the application has been rebuilt or rewritten from this design, it is then necessary to extract the logic that gives the application its particular characteristics. The generic term for such logic is Business Rules. The challenge is to extract or “harvest” these rules from the legacy code.

Traditionally Business analysts or consultants find the rules for a new application by organizing workshops and interviews then manually writing use cases to describe the rules as text. However, for a legacy application all the rules are already there prescribed in the application code - you just have be able to retrieve it.

The problem is that in the vast majority of legacy RPG and COBOL programs, the business rule logic is mixed in with screen handling, database I/O, and flow control. So harvesting these business rules from legacy applications requires knowledge of the application and the language used to implement it, both of which are steadily diminishing resource. Once harvested these rules need to be narrated and indexed, thus providing critical information for any analysts, architect or developer charged with rebuilding a legacy application. The task of harvesting business rules is therefore a highly skilled, labor-intensive, and costly exercise for any organization.

X-Analysis accomplishes this task by automatically scanning the RPG and COBOL programs and 2E model programmatically. It then separates out rule code from the body of the application and identifies, indexes, narrates, and stores business rule logic code into a structured, usable repository. In the final part of the process, it supplies appropriate text narratives to describe these harvested rules.

Once the rules are derived they can be viewed in summary form:
Design recovery & Rebuild With X-Analysis

Note that the description of the business rules is automatically generated it is NOT lifted from existing comments. All the lines in purple with !BRC* have been derived by X-Analysis in the example above the comment simply stated ‘Telephone number’ the derived rule comment looks at how the field is used and validated. NB these Business rules comments are not added back to the RPG source but retained in the X-Analysis repository. This business rule repository can then either be used programatically to generate new code, enhance the built-in documentation, cross referencing, where-used and annotation capabilities, it may be used by new developers as the necessary input for re-specification exercises, whether for new applications or for modifications to the current system.

Once we have derived business rules we can now view the code in multiple ways normal source view - the same as PDM in effect with color coding for the type of statement;

Or inline in the code from where they are derived:
We can view the embedded rules ie. what is really going on in the code as discovered by X-Analysis:

As preparation for moving these rules elsewhere or isolating the rules as psuedocode we can select Extracted Rules;
Design recovery & Rebuild With X-Analysis

The Extracted rules view shows us the code that will be restructured ready for rebuilding:

Notice how the error code `MOVE 'YSU0003' MSGID` that was grayed out has been replaced with `ERROR Y2U0003`
Note that the restructured code view grays out the code that won’t be carried over ie the code that is platform specific. From this view we can press a button to view the restructured code side by side with the original code;

We can view the migrated logic which is the essence of the original code as expressed in a language independent pseudo code.

Notice how the RPG SETLL code has been replaced with a VALIDATE statement to carry out the read against the table on the contract number key.
The final view is the generated code view where we see the code generated to execute the instructions in the pseudocode here it is in Java:

```java
// DSPrev subroutine processing.
private boolean dsprev(String select) throws SQLException {  
    // ZINES subroutine processing.
    private boolean zines() throws SQLException {  
        // VALID subroutine processing.
        private boolean valid(String action) throws SQLException {  
            // If the field "Contract" is zero then it is invalid.
            if (iiseros(conhdr.R.XWORDN)) {  
                setError("XWORDN", "00000010");
                return false;
            }
            // Verify the field 'Contract' against the field 'Contract Header'. If on
            // file then the field 'Contract' is invalid.
            if ("ADD".equals(action)) {
                if (Conhdr.F.recordExists(conhdr.R.XWORDN)) {
                    setError("XWORDN", "T200003");
                    return false;
                }
            }
            // Retrieve the record for the field 'Debtor' from the file 'Purchases'. I
            // not found then it is invalid.
            if (!CustsF.recordExists(conhdr.R.XUBCCD)) {
                setError("XUBCCD", "0000002");
                conhdr.R.XUBCCD = "-";
                return false;
            }
            // Retrieve the record for the field 'Status' from the file 'Order status
            // description'. If not found then it is invalid.
            if (!OrdersF.recordExists(conhdr.R.XUSTAT)) {
                setError("XUSTAT", "000019");
                conhdr.R.XUSTAT = "-";
            }
        }
    }
}
```

Note that whilst this is Java code and thus conceptually far removed from RPG we can by means of naming and comments link this code back to the original system yet it is brand new Java code.

We’ll return to Application rebuilding and code generation later in this document.

**UML Diagramming**

The objective of UML diagrams in this context is to help sketch application designs and to make such sketches portable and reusable in other IDE’s such as Rational, Borland, MyEclipse, etc. The three diagrams automatically generated by X-Analysis are:

Activity Diagram – Activity diagrams illustrate the dynamic nature of a system by modeling the flow of control from activity to activity. An activity represents an operation on some class in the system that results in a change in the state of the system. Typically, activity diagrams are used to model workflow or business processes and internal operation. X-Analysis produces these automatically either from a single program with multiple screens, or a group of programs. Each activity in the diagram represents a usable screen format in the RPG program. A user can also view the extracted Business Rules, relevant to that particular activity/format directly from within the diagram.

Figure 11 – Activity Diagram for a Program
Use Case Diagram – Use Case Diagrams model the functionality of system using actors and use cases. Use cases are services or functions provided by the system to its users. Auto-generated from X-Analysis, this can be used as an alternative view to the Activity Diagram, and also has drill-down capabilities for viewing extracted Business Rules.

Figure 12 – Use Case Diagram for a Program
Class Diagram – Class diagrams are the backbone of all object-oriented methods, including UML. They describe the static structure of a system. Classes represent an abstraction of entities with common characteristics. Associations represent the relationships between classes. An extracted class in a class diagram corresponds to the individual screen formats and all of the specific attributes of that particular format. X-Analysis deduces the links between these classes using a combination of the derived data model, and call or action information extracted from each program.
Figure 14 – Activity Diagram
Producing any of these diagrams from within X-Analysis is as simple as right-clicking on an object and selecting the appropriate option from the menu:

Figure 15 – Producing Diagrams in X-Analysis
Using Design Recovery for Rebuilding

Whilst Design Recovery is very valuable for documentation and application support purposes the real benefits come when the recovered design can be used to modernize or re-develop a system. Reusing existing designs programmatically can provide a dramatic productivity gain in rebuilding an application. While legacy application designs in their entirety might not suit a modern application implementation, design components are often suitable, as long they can be re-used at a sufficiently high level without introducing complexity to the redeveloped application. Therefore, being able to select and enhance, or ignore these at a granular level, removes the inheritance of irrelevant or legacy-specific code constructs, and allows direct access to elements that might have otherwise been deemed unusable in their current form.

NB: This is an important point so worth stressing - this lets us bring across what is useful leaving behind what isn’t relevant and cuts down on duplication.

Another important factor in this scenario is the ability to choose an implementation technology or language that suits the technology constraints or resources specific to a region or organization. The next sections cover how we can use the recovered application design in different ways to effect varying levels of modernization and re-development up to and including a rebuilt system.

Database Modernization - using the Data Model assets

Whilst it has always been possible to access System i data in a relational database like fashion there was originally no way of defining your database in the traditional relational database form with a schema or model. This has meant that most System i applications don’t have an explicitly defined relational database schema or model.

The data model for a legacy application as deduced by X-Analysis can be used to modernize the database and database access as well as providing valuable information for analysis and documentation. Once you have a modernized database you gain a number of advantages:

- Easier access to your data for reporting via Business Intelligence (BI) tools when they use the newly derived Data Model.
- Ability to use modern Object Relational Mapping (ORM) software such as Hibernate for rapid application development in Java and other modern languages.
- Because the database is defined in purely SQL terms rather than in a proprietary file format it becomes portable i.e. it is now an option to consider moving the database to another platform.
- Openness and Standards compliance using Industry standard SQL means that many different tools and applications on multiple platforms can easily access and use your modernized database.
- Improved performance as IBM’s data retrieval efforts have been concentrated on SQL access rather than file based access for many years now.
- Reduced dependency on System i specific skills such as DDS, which may led to cost savings and reduced risk.

© Databorough Limited 2009
Design recovery & Rebuild With X-Analysis

- Data Integrity - Journaling is available for SQL access just as it has always been for file-based access. Constraints and referential integrity can be implemented directly at the database level where they are unavoidable rather than at the program level. Databases triggers allow code to be run before or after records are added, updated or deleted providing an easy way of enforcing compliance, audits, validations and applying business rules.

We’ve now looked at some of the advantages of Database Modernization but how is it actually achieved and how can X-Analysis help the process along?

As previously mentioned historically System i applications have used Data Description Specifications (DDS) to define physical files and associated logical files or access paths. Whilst the files created can of course be accessed using SQL syntax from programs or via JDBC/ODBC the actual definitions bear no relation to SQL. What the process of X-Analysis database modernization does is to replace the DDS definitions with SQL create scripts that build tables and indexes. As we have seen X-Analysis has a complete cross-reference of all files and fields and their relationships and can build the table creation scripts together with the required indexes to optimize the system, your existing programs all still work after this process and without any re-compilation or alteration.

By using X-Analysis to do this automatically, no existing programs need be recompiled or impacted in any way. With the data copying facilities built in to the tool, the transition can be seamless. From this point onwards legacy programs can continue to use native I/O techniques, or be automatically reengineered using Databorough’s X-Ternalize, to use externalized SQL I/O.

X-Analysis can also generate an entire set of CRUD\(^1\) RPG stateless I/O modules to be used as web services for any web or SOA type development.

For IBM’s take on the relative merits of DDS and SQL and the advantages of an SQL created database over one created with DDS see the IBM Redbook “Modernizing IBM eServer iSeries Application Data Access - A Roadmap Cornerstone” which is an excellent reference on this subject.

Modern Data I/O & Persistence – Modern Object Oriented (OO) type development does not mean that relational databases need be abandoned. Indeed, it would be a fairly unwise strategy for a company to throw away its database and the information stored in it, for the sake of OO development. Java is an Object Oriented or OO language. System i databases are relational. Though Java Database Connectivity or, JDBC provides an easy method for accessing relational databases, it is basically a low level API providing only a thin layer of abstraction. Thus complex I/O and data requirements typical of System i applications quickly become very complicated to develop and maintain. JDBC is sufficient for small and medium projects, but is not that well suited for enterprise level applications. Therefore what is required is an Object Relational Mapping (ORM) framework that can act as a mediator between an OO design and a relational database.

The most widely used ORM framework for Java is Hibernate. Hibernate (www.hibernate.org) is a free open source Java package originated and backed by JBoss and Red Hat that makes it easier for Java developers to work with relational databases as it handles what’s known as the persistence layer i.e. the bit that actually reads and writes data to the database. Hibernate has been downloaded at least 3 million times and has gained widespread usage so there are now plenty of books and resources available for it. Hibernate allows Java developers to treat the database as a set of objects

\(^1\) CRUD Create, Read, Update, Delete - a tongue in cheek acronym coined to cover the key table operations any system has have.
like any other object they use, thus dramatically simplifying the code they need to write. For large complicated databases, typical of system i applications, this is naturally a big advantage. It is this, which makes Hibernate one of the most popular persistence frameworks used for enterprise Java applications today.

As a framework Hibernate naturally requires set up and configuration, and the more information that can be supplied in the configuration, the more effectively it can be utilized in development and production. Though DDL Schemas can be imported directly into Hibernate, DDL that describes only the tables and fields of the physical database is only part of the ORM requirement. Relational or foreign key information is obviously the next critical requirement for the Hibernate ORM to work effectively. As explained earlier, the entire legacy relational model derived by X-Analysis can be exported as DDL. This DDL can then be imported directly into Hibernate, thus producing an instant Object relational Map or ORM of the entire legacy application database.

To illustrate Hibernate and X-Analysis lets look at generating ORM objects with X-Analysis this is accessed by a straight forward right click menu;

Hibernate is a very good fit for 2E applications as it is flexible enough to work well with the mnemonic naming without having to use the file/table names as with pure JDBC.
Choose the files you’d like to generate ORM objects for:

X-Analysis generates hibernate mappings, configurations and hibernate java beans - everything required to access those tables from Java;
Generated hibernate xml mappings and hibernate java beans;
Hibernate mapping for purchases table;

```xml
<?xml version="1.0"?>
<!DOCTYPE hibernate-mapping PUBLIC "//Hibernate/Hibernate Mapping DTD 3.0//EN" "http://hibernate.sourceforge.net/hibernate-mapping-3.0.dtd">
<!-- Generated 10-May-2009 17:06:29 by Hibernate Tools 3.2.1.GA -->
<hibernate-mapping>
  <class name="X44D4AT.HBM4Ebean.Purchases" table="CUSTS">
    <id name="XW03CD" type="string">
      <column name="XW03CD" />
      <generator class="assigned" />
    </id>
    <many-to-one name="contractHeader" class="X44D4AT.HBM4Ebean.ContractHeader" 
      column="XW04CCD" not-null="true" unique="true">
      <comment>Customer</comment>
    </many-to-one>
    <property name="xmg4txt" type="string">
      <column name="XMG4TXT" length="40" not-null="true" />
      <comment>Name</comment>
    </property>
    <property name="xmg2cd" type="string">

    </property>
    <property name="xmg3cd" type="string">
      <column name="XMG3CD" length="11" not-null="true" />
      <comment>Related Account</comment>
    </property>
  </class>
</hibernate-mapping>
```

Modern Business Intelligence, Inquiries & Reports – There are many choices when it comes to BI or reporting tools. Almost all of these automatically allow import of the database definition, some provide for the relational or foreign key model of a database, some even try and infer this from the physical implementation of the data base fields and file definitions themselves. The problem with using the file and field names on a System i database, is that they do not match, and they have complex key structures as opposed to UID or sequence keys. The benefits of having an explicitly defined relational and physical model of the database in any of these tools are significant. Almost all reports use some form of file joining information for displaying code descriptions or related information such as list prices on an order for example. Drill-down applications use join or foreign key information to build the navigation links into the reports or queries. The DDL export of the relational and physical model derived by X-Analysis provides a distinct productivity advantage to anyone building reports or BI Applications with any of these tools. It is also possible to populate and build an entire BI application from the data model. The application design is stored as metadata, and then can be generated into reporting tools such as DB2 Web-Query.
Rebuilding the View

In the section, “Recovering Screen Designs” above we described how useful screen design information is extracted into Function Definitions in the X-Analysis repository. These function definitions are effectively input specifications for generating new UI’s or Views. The Modernization Tool Set of X-Analysis actually uses the Function Definitions to automatically, generate JSF/Facelets and Java bean source for each recovered screen design. The generated source code is structured, annotated, simple, industry standard, and ready for maintenance with any Java IDE. Layouts and styles are implemented using CSS, and certain field types implemented with appropriate HTML controls such as date prompts, drop downs, check boxes with corresponding Java Scripting or logic in the Java Bean.

EGL versions are also available for view/controller generation, with future generation options for PHP, C#, and XAML, becoming available from Databorough and other Business Partners.

Actions from the Function definitions translate effectively into links on the generated JSF/Facelets, and these can be implemented with tab, buttons, or any appropriate UI standard demanded by a project. The required logic to invoke these actions is placed in the appropriate methods of the generated Java Bean as described below.

Rebuilding the Controller

The Java bean that drives the JSF/Facelet has standard methods for Data I/O, navigational actions, and for using any residual services that might remain on the legacy server in RPG, COBOL or 2E. This JSF bean has standardized exit points and a set of standard parameters making maintenance and development more efficient and consistent.

A separate call bean is implemented for each transaction group or legacy service program. This call bean provides a standard interface to these reengineered legacy RPG services, and therefore greatly simplifies the controller or JSF bean as it is often referred to. In the case of a set multiple JSF’s that make up a transaction, the call bean also acts as a persistence manager for the transaction.

Reusing Business Rules

The optimum design objective is to move as much of the business rule logic into the Java as possible, thus reducing the dependency on legacy languages. The monolithic architecture of legacy applications produces significant amounts of redundant and duplicate validation and field or calculation logic type business rules. These need to be re-factored if the maintainability of the application maintenance is to be improved – a primary objective of modernization in the first place. Examples of this refactoring process are:

- Centralizing commonly used referential validation rules into the data persistence framework.
- Date formatting logic can be centralized into reusable classes.
- Centralizing commonly used field logic, such as, global tax calculations into reusable classes.
This means that code duplication & redundancy can be almost completely avoided in the modern application. Typically, the only logic recreated in UI specific classes or beans will be context specific calculations field logic such as calculating the value of the order line being captured, along with conditional display or navigation logic for some UI's. These new beans/classes should therefore be fairly simple and easy to maintain by comparison to their legacy counterparts.

X-Analysis provides powerful features as described earlier for narrating, annotating, and carrying out where-used analysis on Business Rules as described in the “Recovering Business Rule Logic” section of this document. These functions combined with the ability to interactively select those rules from the legacy application for reuse in the modern version, dramatically speed up the refactoring process. Rules selected by the user are then placed automatically into the Java bean, with the Pseudo code narrative describing the rule included as annotations in the bean.

The fact that we can easily verify that business rules from the legacy system have been built into the new system provides a high degree of confidence in the new system and is important from a compliance and audit standpoint.

Each legacy program can also be reengineered into a standardized RPG service program as a stored procedure for handling legacy batch services that need not be touched, either temporarily or indefinitely. A Java call bean is created automatically by X-Analysis in this instance, and acts as a wrapper class to this stored procedure, thus greatly simplifying access to legacy services for Java developers. Conversion to EGL is another option available for residual RPG based service logic.
Rebuilding Example

To illustrate how quickly you can begin the rebuilding process lets have a look at a typical iSeries application and rebuild part of it. The key steps are:

1. Identify the parts of the green screen that you want to work with
2. Use X-Analysis Application Areas to break out this part of the system
3. Rebuild the Application Area into your chosen architecture
4. Run the rebuilt application
5. Refine the rebuilt application, tailor to your requirements

Identify what you want to work with

Here’s some screens from our application first the work with customers

These screens are fairly typical of thousands of System i applications which exist today.

**Application Areas**

Having identified that the Work with customers area is what we are interested in the next thing to do is to identify which programs, displays and files are required to make that area work. This would not be a straightforward task if you didn’t have good knowledge of the system.

Fortunately X-Analysis makes this process easy for us by allowing us to easily set up multiple application areas which we can base on a program or programs and specify that we want to include all referenced files and programs:
Once we have our application we can view the objects or programs it contains:

This is a very powerful technique and allows rapid prototyping and development without having to develop the whole system in one go. The application areas you create can be integrated together into a larger structure and displayed using the application area diagram.
Rebuild the Application

Working with the application area that we have just created we can build a web application directly.

We can choose the programs to include, the application architecture we want to use Java or EGL (PHP and .Net under development), whether to include Business Rule logic or not and the type of data access mechanism we wish to use JDBC or ORM (Hibernate).
When we press OK here a new Java Web application is generated for us.

As we can see in the screen shot to the left the application that is generated comes complete with the necessary script files to build it for different application servers eg. Apache Tomcat and WebSphere.

The code is structured in a logical manner with hibernate beans or data beans according to whether we chose the ORM option or not.

Similarly if we opened up the classes and the JSF pages produced we would see that they have names which can clearly tie them back to the original application even though this is brand new code.

Once this application is built we can deploy it to the application server of our choice and start to use the application.

You can either go straight to a browser and navigate to a page, but an easier way is to use the built in integration with X-Analysis.

If we go back to the X-Analysis view of our application area and bring up the programs, if we select WWCUSTS and right click we have options to allow us to display the corresponding JSF page as can be seen in this screen shot:

© Databorough Limited 2009
When we click on the Execute JSF we get the rebuilt work with Customers page:
Following the screen flow we had earlier on the green screen side here’s the Work with Customers screen.

The pages that have been generated are fully functional however you will probably want to alter the appearance to match your standard pages and perhaps add links and so on to integrate the pages with other systems. The pages all use Cascading Style Sheets (CSS) to control their look and feel and positioning so changes are easy to make.

Regardless of your opinion on the aesthetics of the generated screens you will agree that the basic pages are not bad for zero coding and just a few clicks!!

Following the screen flow we had earlier on the green screen side here’s the Work with Orders screen.
Completing the Modernization Process

Some mention should at least be made on some of the tasks remaining to complete the application rebuild. Rather than explain how to do these in detail in this white paper, the most relevant points have been summarized below. There will be a subsequent white paper from Databorough that will elaborate on these points. There is no shortage of articles and books on these aspects generally available to modern software architects. Some useful articles listed in the “Additional Resources & Information” section below, cover some of these subjects.
**Surrounding Application Framework**

In most cases, it will be desirable to replace some of the System i application constructs with JEE or other equivalents.

- File Overrides
- LDA type constructs
- Soft Security
- Commitment Control

**Look & Feel & UI Standards**

Green screen applications have always been optimized for rapid data entry with such helpful features as tabbing between fields and Field exit field completion, it is perfectly possible to make a web application work well for data entry but it requires effort and as was often the case with windows applications it isn’t always done well - as an example it is common to come across web applications where the tab order is not correctly set and tabbing can take you to images or almost anywhere but the field you were hoping for!

The task of designing new interfaces for the modernized applications should not be underestimated you can’t simply rely on the ‘cool’ factor of the web and the colorful and sophisticated look and feel that style sheets enable do not guarantee a usable interface.

To illustrate some of the issues consider the case of an updatable sub-file grid that a user might enter a series of transactions into which there happen to be some transaction code fields included. As a global UI standard, the decision might be to replace code fields with drop-down combo boxes using the descriptor rather than the code itself. This might look good but cause big problems in performance (both from preparation of the page and also the sheer size of the page being transmitted) when populating the drop downs individually for each row in the grid, before the user even starts to enter data. It might also be a lot slower for the user to drop down a list of 300 codes and select the required one with a mouse for each row, as opposed to entering a two or three digit well known code into it - this would also be very frustrating for existing users and as we know new systems can fail because of user resistance.

When we analyze this scenario we see that in the green screen application we have a system which can be operated quickly by the users using only the keyboard and is very responsive - though it would appear intimidating and strange to new users used only to Windows or web applications - the challenge is to build a new interface which is accessible, intuitive and easy to use for new users whilst allowing the existing users to apply their knowledge of the system to get around it quickly and with good performance and responsiveness.

Taking the example mentioned earlier where we wish to produce a new application where a user enters transactions involving entering codes, in the green screen world this would typically just be an input field with possibly and F4 prompt option to show the allowable values. As alluded to above in the web world the first thought is often to convert this type of construct to a drop down combo box like this example from the IBM Power site:
This can be cumbersome if there are many values and unless you have only a few codes beginning with each number or letter (in most browsers once the focus is on a drop down box typing a letter or number will position the cursor at the first matching entry in the list) keyboard navigation is limited and can involve a lot of scrolling.

This example looks quite cumbersome, but imagine if it had several hundred options and you had to repeat the same process many times on each page! So how can we improve the usability and provide help for new users at the same time? Most web applications that have been developed from older applications use technologies dating from the birth of the web (Web 1.0) and are analogous to main-frame technologies i.e. the browser is a dumb terminal you enter data then press enter, then get feedback on errors etc. Web 2.0 technologies which I shall address shortly are similar in principle to Mini computers like the iSeries the terminal or browser can communicate in real-time with the computer as the data is being entered providing instant feedback.

For the purposes of this paper when addressing Web 2.0 we are referring to AJAX - Asynchronous JavaScript and XML. Ajax is a term that was coined in 2005 as a tipping point was reached where most web browsers in use had a lowest common denominator set of capabilities across CSS, JavaScript, XML and XHTML which enabled implementation of rich web applications that communicate with a server in the background without stopping the page displaying. Google Maps and Google Suggest are good examples of Ajax in action and helped popularize the concept, Google Maps uses Ajax to prefetch the map images around the area you’re looking at which allows fast scrolling, Google Suggest populates a list of search terms based on the letters you’ve typed.

Ajax allows us to design a flexible system which can support both new and existing users. For new users or anyone needing a reminder of keystroke we can have a help icon or question mark beside the field if clicked a windows will appear allowing the user to choose the appropriate code, depending on the complexity of your codes you may wish to add a wizard or step by step facility which asks questions that narrow the range of codes. For the experienced users you have several choices including;

Let the user enter a code and validate it when they leave the field.
Let the user type in one or more characters of the code and then show a dynamic list for them to choose from based on the character(s) they have entered.

The best choice is likely to be to combine the two approaches with a variable delay on the dynamic list so we don’t waste system time generating lists when the user knows the whole code, only prompting when it looks like it would be useful.

Ajax has become widely used since 2005 and a number of frameworks exist to make their use easier and in some cases automatically for example JSON - JavaScript Object Notation and GWT - Google Web Toolkit.

Practical usability and look and feel designs go hand in hand, and require knowledge and information about modern UI controls and legacy UI patterns, which can also be extracted as part of the X-Analysis documentation facilities.
Summary

Comprehensive, accurate, and current documentation of a legacy application improves quality, productivity and reduces risk, for any maintenance, modernization or rebuild IT project. The risk associated with maintaining large complex legacy application, with a rapidly diminishing set of legacy skills, can be largely mitigated by access to such documentation.

Understanding and mapping the relevance of existing designs, and quantifying the scope and metrics of an application, is the first step in ANY modernization project, even if the application is to be replaced. Design constructs such as the data model can be used for support, development, and testing tasks such as test data extraction. Source change management can be vastly improved by powerful cross-referencing functionality.

Legacy design constructs can be used passively in the form of information they represent, and programmatically to radically accelerate application rebuilds; a requirement for achieving true long-term application modernization. A combination of both allows optimum use of internal and external resources and existing design assets.

X-Analysis delivers against all of these concepts. 20+ years of development effort, ensures that virtually any legacy application can be automatically reverse engineered onto a high-level design.
